Notice that in some nodes (like between R 1 and R 2) the current is the same going in as it is coming out.At other nodes (specifically the three-way junction between R 2, R 3, and R 4) the main (blue) current splits into two different ones. That's the key difference between series and parallel!. Series Circuits Defined. Two components are in series if they share a common node and if the same ...

In a parallel circuit, each device is connected in a manner such that a single charge passing through the circuit will only pass through one of the resistors. This Lesson focuses on how this type of connection affects the relationship between resistance, current, and voltage drop values for individual resistors and the overall resistance, current, and voltage drop values for the entire circuit.

Parallel Circuits . A parallel circuit is one that has two or more paths for the electricity to flow, the loads are parallel to each other. If the loads in this circuit were light bulbs and one blew out, there is still current flowing to the others because they are still in a direct path from the negative to positive terminals of the battery. ...

In a parallel circuit the source current divides among the available paths. The behavior of current in parallel circuits will be shown by a series of illustrations using example circuits with different values of resistance for a given value of applied voltage. Part (A) of figure 3-40 shows a basic series circuit.

**Current in a Parallel Circuit - tpub.com**  
Series and Parallel Circuits Electrical current is manipulated in the construction of parallel and series circuits. A series circuit is one in which the current has only one path to take from the negative terminal of the battery through the load and back to the positive terminal. The circuit no longer works if one bulb or battery is disconnected.
